This is just an excerpt of a full-length report for this pathway. To access the complete report, please download it at the Reactome Textbook.

28/10/2022
**Introduction**

Reactome is open-source, open access, manually curated and peer-reviewed pathway database. Pathway annotations are authored by expert biologists, in collaboration with Reactome editorial staff and cross-referenced to many bioinformatics databases. A system of evidence tracking ensures that all assertions are backed up by the primary literature. Reactome is used by clinicians, geneticists, genomics researchers, and molecular biologists to interpret the results of high-throughput experimental studies, by bioinformaticians seeking to develop novel algorithms for mining knowledge from genomic studies, and by systems biologists building predictive models of normal and disease variant pathways.

The development of Reactome is supported by grants from the US National Institutes of Health (P41 HG003751), University of Toronto (CFREF Medicine by Design), European Union (EU STRP, EMI-CD), and the European Molecular Biology Laboratory (EBI Industry program).

Reactome database release: 82

This document contains 1 pathway and 6 reactions (see Table of Contents)
Small nuclear ribonucleoproteins (snRNPs) are crucial for pre-mRNA processing to mRNAs. Each snRNP contains a small nuclear RNA (snRNA) and an extremely stable core of seven Sm proteins. The U6 snRNA differs from the other snRNAs; it binds seven Sm-like proteins and its assembly does not involve a cytoplasmic phase. The snRNP biogenesis pathway for all of the other snRNAs is complex, involving nuclear export of snRNA, Sm-core assembly in the cytoplasm and re-import of the mature snRNP. The assembly of the snRNA:Sm-core is carried out by the survival of motor neurons (SMN) complex. The SMN complex stringently scrutinizes RNAs for specific features that define them as snRNAs and binds the RNA-binding Sm proteins.

The snRNAs, except U6 snRNA, are transcribed by RNA polymerase II, co-transcriptionally capped and exported rapidly to the cytoplasm in association with a cap-binding complex and the export factor PHAX.

Followed by: snRNP complex assembly

The survival of motor neurons (SMN) complex binds to Sm proteins and small nuclear RNAs (snRNAs) in the cytoplasm. Sm is part the SMN multiprotein complex that contains Gemins 2 – 7, including the DEAD-box RNA helicase Gemin3. The binding of the SMN complex to the snRNAs depends on the presence of specific, high-affinity (nanomolar) binding domains in the snRNAs. The SMN complex binds the Sm proteins through the Sm domains interaction with the Gemins, the TUDOR domain, and through unique arginine- and glycine-rich (RG) domains found in three of these, SmB, SmD1 and SmD3. The association with RG domains is strongly enhanced by the post-translational symmetric dimethylation of specific arginines in these domains, a process that is carried out by the methylosome (JBP1 or PRMT5) complex.

To facilitate snRNP assembly, the SMN complex must bring together the Sm proteins and a Sm-site-containing snRNA. The SMN:Sm protein complex binds to the m7G capped snRNAs in the cytoplasm.

SARS-CoV-2 nonstructural protein 16 (nsp16) binds to the 5′ splice site recognition sequence of U1 snRNA and the branchpoint recognition site of U2 snRNA, both parts of the spliceosome, disrupting global mRNA splicing (Banerjee et al, 2020).

The nuclear import signal has two parts; Cap hypermethylation triggers nuclear import via snurportin1 binding and by receptor recognition of the Sm proteins. Snurportin1 (SPN) is an adaptor that links the assembled snRNP to the nuclear transport machinery, recruiting importin beta for nuclear import. The import receptor that recognizes the Sm proteins is not yet known.

snRNP nuclear import and release

**Location:** snRNP Assembly

**Stable identifier:** R-HSA-191830

**Type:** dissociation

**Compartments:** nuclear envelope

A properly assembled Sm core and the m3G cap structure are prerequisites for small nuclear ribonucleoprotein (snRNP) import into the nucleus. Once imported into the nucleus, the snRNPs are initially concentrated in Cajal bodies (CBs), where there is further processing of the snRNAs plus binding of additional proteins, from CRBs they transit to "speckles", from where they are engaged for pre-mRNA splicing. The SMN complexes in the nucleus are found throughout the nucleoplasm but are particularly concentrated in Gems, the "twins" of the snRNP-rich CBs.
